

Methods for Reconstructing Paleo Food Webs

Tanya Strydom ¹; Andrew P. Beckerman ¹

Abstract: TODO.

Keywords: food web, network construction, scientific ignorance

0.1 Why build paleo food webs?

- Because its interesting?
- Value in using hindcasting to aid in forecasting. *e.g.*, the Toarcian ms (Dunhill et al., 2024) shows how we can use these paleo communities to understand trophic-level responses to extinctions.

0.2 How do we do it?

- There is an evolving body of work that focuses on developing tools specifically for the task of predicting food webs.
- There are a handful that have been developed specifically in the context of paleo settings *e.g.*, TODO but we can also talk about those that might have been developed/tested in contemporary settings but still have applicability in paleo ones.
- Different underlying theory though
 - Focus here on the idea of different ‘currencies’ but also aggregations - energy vs compatibility.
- Insert brief overview of the different methods as they pertain to approach (so the T4T triangle)
- Challenges we face (even in contemporary settings)?
 - keep high level - I think the argument here should fall more in the data trade offs...

0.3 Understanding how networks are different

It is important to be aware that networks can be configured in different ways depending on how the interactions are defined (Strydom, in prep). Basically we have metawebs, which represent *potential* interactions, and realised networks, which represent the subset of potential that are realised as a result of community and environmental context.

0.4 Challenges specific to paleo communities/networks

Although there are a suite of tools and methods that have been developed to predict species interactions and networks they will not all be suitable for the prediction of paleo communities. Some of these include the fact that the fossil record is incomplete/preservation is biased [REF] which means that we have an incomplete picture of the entire community. Fossils are 2D and only represent specific ‘parts’ of an individual (hard and bone-y bits), this means we don’t have a complete picture of the physical traits of species *e.g.*, no body mass (but yes size), behaviours, or ability to construct well resolved phylogenetic trees the deeper we go back in

time. Also owing to the patchy nature of fossils one often has to aggregate over large spatial scales, and also fossils are preserved in 2D so no *real* idea of spatial arrangements, compounded that fossils aren't necessarily conserved/found 'in situ' but can be moved (*e.g.*, alluvial deposits). Methodologically speaking some tools that 'learn' from contemporary communities (*e.g.*, Strydom, Caron) will become 'worse' the further one goes back in time since species then look very different from now but can still be useful for 'recent' communities (*e.g.*, fricke).

0.5 Dataset Overview

- Species
- Time/space
- And probably some other paleo things that will be relevant...

0.6 Methods to use

Paleo food web inference model (PFIM; Shaw et al. (2024)): uses a series of rules for a set of trait categories (such as habitat and body size) to determine if an interaction can feasibly occur between a species pair. If all conditions are met for the different rule classes then an interaction is deemed to be feasible. The original work put forward in Shaw et al. (2024) also includes a 'downsampling' step developed by Roopnarine (2006) that uses a power law, defined by the link distribution, to 'prune' down some of the links.

Allometric diet breadth model (ADBM; Petchey et al. (2008)): The ADBM is rooted in feeding theory and allocates the links between species based on energetics, which predicts the diet of a consumer based on energy intake. This means that the model is focused on predicting not only the number of links in a network but also the arrangement of these links based on the diet breadth of a species, where the diet (K) is defined as follows:

$$K = \frac{\sum_{i=1}^k \lambda_{ij} E_i}{1 + \sum_{i=1}^k \lambda_{ij} H_{ij}} \quad (1)$$

where λ_{ij} is the handling time, which is the product of the attack rate A_i and resource density N_i , E_i is the energy content of the resource and H_{ij} is the ratio handling time, with the relationship being dependent on the ratio of predator and prey bodymass as follows:

$$H_{ij} = \frac{h}{b - \frac{M_i}{M_j}} if \frac{M_i}{M_j} < b$$

52 or

$$H_{ij} = \infty \geq b$$

53 Refer to Petchey et al. (2008) for more details as to how these different terms are parametrised.

54 **Body size ratio model** (Rohr et al., 2010): Determines feeding interactions using the ratio between
 55 consumer and resource body sizes - which supposedly stems from niche theory (still trying to reconcile that
 56 myself). The probability of a link existing between a consumer and resource (in its most basic form) is defined
 57 as follows:

$$P_{ij} = \frac{p}{1 + p}$$

58 where

$$p = \exp[\alpha + \beta \log(\frac{M_i}{M_j}) + \gamma \log^2(\frac{M_i}{M_j})] \quad (2)$$

59 The original latent-trait model developed by Rohr et al. (2010) also included an additional latent trait term
 60 $v_i \delta f_j$ however for simplicity we will use Equation 2 as per Yeakel et al. (2014) Based on Rohr et al. (2010) it
 61 is possible to estimate the parameters α , δ , and γ using a GLM but we will use the parameters from Yeakel
 62 et al. (2014), which was ‘trained’ on the Serengeti food web data and are as follows: $\alpha = 1.41$, $\delta = 3.75$, and
 63 $\gamma = 1.87$.

64 **Niche model** (Williams & Martinez, 2000): The niche model introduces the idea that species interactions
 65 are based on the ‘feeding niche’ of a species. Broadly, all species are randomly assigned a ‘feeding niche’ range
 66 and all species that fall in this range can be consumed by that species (thereby allowing for cannibalism).
 67 The niche of each species is randomly assigned and the range of each species’ niche is (in part) constrained by
 68 the specified connectance of the network. The niche model has also been modified, although it appears that
 69 adding to the ‘complexity’ of the niche model does not improve on its ability to generate a more ecologically
 70 ‘correct’ network (Williams & Martinez, 2008).
